Chapter 5 - General Procedures

5.1 Function Procedures
5.2 Sub Procedures, Part I
5.3 Sub Procedures, Part II
5.4 Modular Design
Devices for Modularity

Visual Basic has two devices for breaking problems into smaller pieces:

- Function procedures
- Sub procedures
5.1 Function Procedures

• Functions Having One Parameter
• Passing by Value
• Restriction on Data Types
• Functions Having Several Parameters
• Boolean-Valued Functions
Some Built-In Functions

Function: Int
Example: Int(2.6) is 2
Input: number
Output: number

Function: Math.Round
Example: Math.Round(1.23, 1) is 1.2
Input: number, number
Output: number
Some Built-In Functions (continued)

Function: Chr
Example: Chr(65) is A
Input: number
Output: string

Function: Asc
Example: Asc("Apple") is 65
Input: string
Output: number
Function Procedures

• Function procedures (aka user-defined functions) always return one value

• Syntax:

```plaintext
Function FunctionName(var1 As Type1,
                        var2 As Type2,
                        ...) As ReturnDataType

  statement(s)

  Return expression

End Function
```
Function FtoC(t As Double) As Double
    'Convert Fahrenheit temp to Celsius
    Return (5 / 9) * (t - 32)
End Function
Header of the FtoC Function Procedure

```
Function FtoC(t As Double) As Double
```

- Function name: `FtoC`
- Parameter: `t` of type `Double`
- Data type of parameter: `Double`
- Data type of value returned: `Double`
Example 1: Form

Temperature

Temperature (Fahrenheit): 

Convert to Celsius

Temperature (Celsius): 

txtTempF

txtTempC
Example 1: Code

```vbnet
Private Sub btnConvert_Click(...) _
Handles btnConvert.Click
    Dim fahrenheitTemp, celsiusTemp As Double
    fahrenheitTemp = CDb1(txtTempF.Text)
    celsiusTemp = FtoC(fahrenheitTemp)
    txtTempC.Text = CStr(celsiusTemp)
End Sub

Function FtoC(t As Double) As Double
    Return (5 / 9) * (t - 32)
End Function
```
Example 1: Output

![Temperature Conversion Dialogue Box](image-url)
Function FirstName(fullName As String) As String

'Extract first name from full name
Dim firstSpace As Integer
firstSpace = fullName.IndexOf(" ")
Return fullName.Substring(0, firstSpace)
End Function
Example 2: Form

[Diagram of a form with text boxes for "Full name" and "First name"]

- `txtFullName`
- `txtFirstName`
Example 2: Code

Private Sub btnDetermine_Click(...) _
    Handles btnDetermine.Click
    Dim fullName As String
    fullName = txtFullName.Text
    txtFirstName.Text = FirstName(fullName)
End Sub

Function FirstName(fullName As String) As String
    Dim firstSpace As Integer
    firstSpace = name.IndexOf(" ")
    Return name.Substring(0, firstSpace)
End Function
Example 2: Output

![Diagram showing a name input dialogue box with full name as Franklin Delano Roosevelt, and the determined first name as Franklin.]
User-Defined Function Having Several Parameters

Function Pay(wage As Double, 
            hrs As Double) As Double

    Dim amt As Double 'amount of salary
    Select Case hrs
        Case Is <= 40
            amt = wage * hrs
        Case Is > 40
            amt = wage * 40 + (1.5 * wage * (hrs - 40))
    End Select
    Return amt
End Function
Example 3: Form

Weekly Pay

Hourly wage: [textbox]

Hours worked: [textbox]

Calculate Earnings for the Week

Earnings: [textbox]

txtWage

txtHours

txtEarnings
Example 3: Partial Code

Private Sub btnCalculate_Click(...) _
Handles btnCalculate.Click

Dim hourlyWage, hoursWorked As Double
hourlyWage = CDb1(txtWage.Text)
hoursWorked = CDb1(txtHours.Text)
txtEarnings.Text =

    (Pay(hourlyWage, hoursWorked)).ToString("C")

End Sub
Example 3: Output

Weekly Pay

Hourly wage: 14.50

Hours worked: 45

Calculate Earnings for the Week

Earnings: $688.75
User-Defined Boolean-Valued Function

Function IsVowelWord(word As String) As Boolean

    If word.IndexOf("A") = -1 Then
        Return False
    End If

    If word.IndexOf("U") = -1 Then
        Return False
    End If

    Return True
End Function
5.2 Sub Procedures, Part I

- Defining and Calling Sub Procedures
- Variables and Expressions as Arguments
- Sub Procedures Having No Parameters
- Sub Procedures Calling Other Sub Procedures
General Form of Sub Procedure

Sub ProcedureName(par1 As Type1, par2 As Type2, _
...,
parN As TypeN)

statement(s)

End Sub
Calling a Sub Procedure

• The statement that invokes a Sub procedure is referred to as a calling statement.
• A calling statement looks like this:

   `ProcedureName(arg1, arg2, ..., argN)`
Naming Sub Procedures

The rules for naming Sub procedures are the same as the rules for naming variables.
Passing Values

DisplaySum(2, 3)

Sub DisplaySum(num1 As Double, num2 As Double)
    Dim z As Double
    z = num1 + num2
    lstOutput.Items.Add("The sum of " & num1 & " and " & num2 & " is " & z & ".")
End Sub

• In the Sub procedure, 2 will be stored in num1 and 3 will be stored in num2
Arguments and Parameters

$\text{Sum}(2, 3)$

arguments

$\text{Sub DisplaySum}(\text{num1 As Double, num2 As Double})$

parameters
Several Calling Statements

DisplaySum(2, 3)
DisplaySum(4, 6)
DisplaySum(7, 8)

Output:
The sum of 2 and 3 is 5.
The sum of 4 and 6 is 10
The sum of 7 and 8 is 15.
Passing Strings and Numbers

Sub Demo(state As String, pop As Double)
    lstOutput.Items.Add = state &
    " has population " & pop & " million."
End Sub

Note: The statement Demo(38, "CA") would not be valid. The types of the arguments must be in the same order as the types of the parameters.
Variables and Expressions as Arguments

Dim s As String = "CA"
Dim p As Double = 19
Demo(s, 2 * p)

Sub Demo(state As String, pop As Double)
    lstOutput.Items.Add = state &
    " has population " & pop & " million."
End Sub

**Note:** The argument names need not match the parameter names. For instance, s versus state.
Sub DescribeTask()
    lstBox.Items.Clear()
    lstBox.Items.Add("This program displays")
    lstBox.Items.Add("the name and population")
    lstBox.Items.Add("of a state.")
End Sub
Sub Procedure Calling Another Sub Procedure

Private Sub btnDisplay_Click(...) Handles btnDisplay.Click
    Demo("CA", 38)
End Sub

Sub Demo(state As String, pop As Double)
    DescribeTask()
    lstOutput.Items.Add(""
    lstOutput.Items.Add = state & " has population " & pop & " million."
End Sub
This program displays
the name and population
of a state.

CA has population 38 million.
5.3 Sub Procedures, Part II

- Passing by Value
- Passing by Reference
- Sub Procedures that Return a Single Value
- Scope and Lifetime of Variables and Constants
- Debugging
ByVal and ByVal

• Parameters in Sub procedure headers can be proceeded by ByVal
• ByVal stands for By Value
Passing by Value

- When a variable argument is passed to a parameter not preceded with ByRef, just the value of the argument is passed.
- After the Sub procedure terminates, the variable has its original value.
Example

Public Sub btnOne_Click(...) Handles _
    btnOne.Click

    Dim n As Double = 4
    Triple(n)
    txtBox.Text = CStr(n)

End Sub

Sub Triple(num As Double)
    num = 3 * num
End Sub

Output: 4
Public Sub btnOne_Click (...) Handles _
    btnOne.Click

    Dim num As Double = 4
    Triple(num)
    txtBox.Text = CStr(num)
End Sub

Sub Triple(num As Double)
    num = 3 * num
End Sub

Output: 4
Passing by Reference

• When a variable argument is passed to a parameter preceded by ByRef, the parameter is given the same memory location as the argument.

• After the Sub procedure terminates, the variable has the value of the parameter.
Example

Public Sub btnOne_Click (...) Handles _
    btnOne.Click

    Dim num As Double = 4
    Triple(num)
    txtBox.Text = CStr(num)
End Sub

Sub Triple(ByRef num As Double)
    num = 3 * num
End Sub

Output: 12
Example: num → n

Private Sub btnOne_Click(...) Handles __
    btnOne_Click
        Dim n As Double = 4
        Triple(n)
        txtBox.Text = CStr(n)
    End Sub

Sub Triple(ByRef num As Double)
    num = 3 * num
End Sub

Output: 12
Most Common Use of ByRef: Get Input

Sub InputData(ByRef wage As Double, 
               ByRef hrs As Double)
    wage = CDb1(txtWage.Text)
    hrs = CDb1(txtHours.Text)
End Sub
Sub Procedures that Return a Single Value with ByRef

- Should be avoided
- Usually can be replaced with a Function procedure
Lifetime and Scope of a Variable

- **Lifetime**: Period during which it remains in memory.
- **Scope**: In Sub procedures, defined same as in event procedures.
- Suppose a variable is declared in procedure A that calls procedure B. While procedure B executes, the variable is alive, but out of scope.
Debugging

- Programs with Sub procedures are easier to debug
- Each Sub procedure can be checked individually before being placed into the program
Comparing Function Procedures with Sub Procedures

- Sub procedures are accessed using a calling statement.
- Functions are called where you would expect to find a literal or expression.
- For example:
  - `result = functionCall`
  - `lstBox.Items.Add (functionCall)`
Functions vs. Procedures

- Both can perform similar tasks
- Both can call other procedures
- Use a function when you want to return one and only one value
5.4 Modular Design

- Top-Down Design
- Structured Programming
- Advantages of Structured Programming
- Object-Oriented Programming
Design Terminology

- Large programs can be broken down into smaller problems
- *divide-and-conquer* approach called *stepwise refinement*
- Stepwise refinement is part of *top-down design* methodology
Top-Down Design

- General problems are at the top of the design
- Specific tasks are near the end of the design
- Top-down design and structured programming are techniques to enhance programmers' productivity
Top-Down Design Criteria

1. The design should be easily readable and emphasize small module size.
2. Modules proceed from general to specific as you read down the chart.
3. The modules, as much as possible, should be single minded. That is, they should only perform a single well-defined task.
4. Modules should be as independent of each other as possible, and any relationships among modules should be specified.
Beginning of Hierarchy Chart

Car loan

Get input  Make calculations  Display results
Detailed Hierarchy Chart

Car loan

- Get input
  - Get amount
  - Get duration
  - Get interest rate

- Make calculations
  - Compute monthly payment
  - Compute 1st month's interest

- Display results
  - Display headings
  - Display amounts

- Calculate number of months
- Apply payment formula
Structured Programming

Control structures in structured programming:

- **Sequences**: Statements are executed one after another.
- **Decisions**: One of two blocks of program code is executed based on a test of a condition.
- **Loops (iteration)**: One or more statements are executed repeatedly as long as a specified condition is true.
Advantages of Structured Programming

Goal to create correct programs that are easier to

• write
• understand
• modify
Easy to Write

- Allows programmer to first focus on the big picture and take care of the details later
- Several programmers can work on the same program at the same time
- Code that can be used in many programs is said to be reusable
Easy to Debug

• Procedures can be checked individually
• A **driver** program can be set up to test modules individually before the complete program is ready.
• Using a driver program to test modules (or stubs) is known as **stub testing**.
Easy to Understand

• Interconnections of the procedures reveal the modular design of the program.
• The meaningful procedure names, along with relevant comments, identify the tasks performed by the modules.
• The meaningful procedure names help the programmer recall the purpose of each procedure.
Easy to Change

• Because a structured program is self-documenting, it can easily be deciphered by another programmer.
Object-Oriented Programming

- an encapsulation of data and code that operates on the data
- objects have properties, respond to methods, and raise events.
