1

#### Local Variables

• A variable declared in the body of a function is said to be *local* to the function:

```
int sum_digits(int n)
{
    int sum = 0;    /* local variable */
    while (n > 0) {
        sum += n % 10;
        n /= 10;
    }
    return sum;
}
```

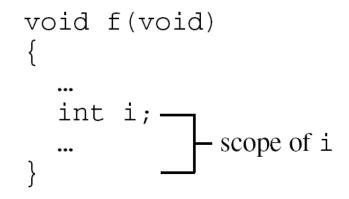

#### **Local Variables**

- Default properties of local variables:
  - Automatic storage duration. Storage is
     "automatically" allocated when the enclosing function is called and deallocated when the function returns.
  - *Block scope.* A local variable is visible from its point of declaration to the end of the enclosing function body.

#### Local Variables

• Since C99 doesn't require variable declarations to come at the beginning of a function, it's possible for a local variable to have a very small scope:

Copyright © 2008 W. W. Norton & Company. All rights reserved.

4

## **Static Local Variables**

- Including static in the declaration of a local variable causes it to have *static storage duration*.
- A variable with static storage duration has a permanent storage location, so it retains its value throughout the execution of the program.
- Example:

```
void f(void)
{
   static int i; /* static local variable */
...
}
```

• A static local variable still has block scope, so it's not visible to other functions.

#### Parameters

- Parameters have the same properties—automatic storage duration and block scope—as local variables.
- Each parameter is initialized automatically when a function is called (by being assigned the value of the corresponding argument).

#### **External Variables**

- Passing arguments is one way to transmit information to a function.
- Functions can also communicate through *external variables*—variables that are declared outside the body of any function.
- External variables are sometimes known as *global variables*.

### **External Variables**

- Properties of external variables:
  - Static storage duration
  - File scope
- Having *file scope* means that an external variable is visible from its point of declaration to the end of the enclosing file.

- To illustrate how external variables might be used, let's look at a data structure known as a *stack*.
- A stack, like an array, can store multiple data items of the same type.
- The operations on a stack are limited:
  - **Push** an item (add it to one end—the "stack top")
  - *Pop* an item (remove it from the same end)
- Examining or modifying an item that's not at the top of the stack is forbidden.

- One way to implement a stack in C is to store its items in an array, which we'll call contents.
- A separate integer variable named top marks the position of the stack top.
  - When the stack is empty, top has the value 0.
- To *push* an item: Store it in contents at the position indicated by top, then increment top.
- To *pop* an item: Decrement top, then use it as an index into contents to fetch the item that's being popped.

- The following program fragment declares the contents and top variables for a stack.
- It also provides a set of functions that represent stack operations.
- All five functions need access to the top variable, and two functions need access to contents, so contents and top will be external.

```
#include <stdbool.h> /* C99 only */
#define STACK_SIZE 100
/* external variables */
int contents[STACK_SIZE];
int top = 0;
void make_empty(void)
{
  top = 0;
}
bool is_empty(void)
{
  return top == 0;
}
```

### Example: Using External Variables to Implement a Stack

```
bool is full (void)
  return top == STACK SIZE;
void push(int i)
  if (is full()
    stack overflow();
  else
    contents[top++] = i;
int pop(void)
  if (is empty())
    stack underflow();
  else
    return contents [--top];
PROGRAMMING
                          13
```

A Modern Approach Second Edition

Copyright © 2008 W. W. Norton & Company. All rights reserved.

- External variables are convenient when many functions must share a variable or when a few functions share a large number of variables.
- In most cases, it's better for functions to communicate through parameters rather than by sharing variables:
  - If we change an external variable during program maintenance (by altering its type, say), we'll need to check every function in the same file to see how the change affects it.
  - If an external variable is assigned an incorrect value, it may be difficult to identify the guilty function.
  - Functions that rely on external variables are hard to reuse in other programs.

- Don't use the same external variable for different purposes in different functions.
- Suppose that several functions need a variable named i to control a for statement.
- Instead of declaring *i* in each function that uses it, some programmers declare it just once at the top of the program.
- This practice is misleading; someone reading the program later may think that the uses of *i* are related, when in fact they' re not.

- Make sure that external variables have meaningful names.
- Local variables don't always need meaningful names: it's often hard to think of a better name than i for the control variable in a for loop.

- Making variables external when they should be local can lead to some rather frustrating bugs.
- Code that is supposed to display a 10 × 10 arrangement of asterisks: int i;

```
void print_one_row(void)
{
  for (i = 1; i <= 10; i++)
    printf("*");
}
void print_all_rows(void)
{
  for (i = 1; i <= 10; i++) {
    print_one_row();
    printf("\n");
  }
}</pre>
```

• Instead of printing 10 rows, print\_all\_rows prints only one.

### Program: Guessing a Number

• The guess.c program generates a random number between 1 and 100, which the user attempts to guess in as few tries as possible:

Guess the secret number between 1 and 100. A new number has been chosen. Enter guess: 55 Too low; try again. Enter guess: 65 Too high; try again. Enter guess: 60 Too high; try again. Enter guess: 58 You won in 4 guesses!

## **Program: Guessing a Number**

```
Play again? (Y/N) \underline{y}
```

A new number has been chosen. Enter guess: <u>78</u> Too high; try again. Enter guess: <u>34</u> You won in 2 guesses!

```
Play again? (Y/N) \underline{n}
```

- Tasks to be carried out by the program:
  - Initialize the random number generator
  - Choose a secret number
  - Interact with the user until the correct number is picked
- Each task can be handled by a separate function.

#### guess.c

## Program: Guessing a Number

- Although guess.c works fine, it relies on the external variable secret\_number.
- By altering choose \_new\_secret\_number and read\_guesses slightly, we can move secret\_number into the main function.
- The new version of guess.c follows, with changes in **bold**.

#### guess2.c

/\* Asks user to guess a hidden number \*/

```

#### Blocks

- In Section 5.2, we encountered compound statements of the form
  - { statements }
- C allows compound statements to contain declarations as well as statements:
  - { declarations statements }
- This kind of compound statement is called a *block*.

#### **Blocks**

• Example of a block:

```
if (i > j) {
    /* swap values of i and j */
    int temp = i;
    i = j;
    j = temp;
}
```

### Blocks

- By default, the storage duration of a variable declared in a block is automatic: storage for the variable is allocated when the block is entered and deallocated when the block is exited.
- The variable has block scope; it can't be referenced outside the block.
- A variable that belongs to a block can be declared static to give it static storage duration.

### Blocks

- The body of a function is a block.
- Blocks are also useful inside a function body when we need variables for temporary use.
- Advantages of declaring temporary variables in blocks:
  - Avoids cluttering declarations at the beginning of the function body with variables that are used only briefly.
  - Reduces name conflicts.
- C99 allows variables to be declared anywhere within a block.

## Scope

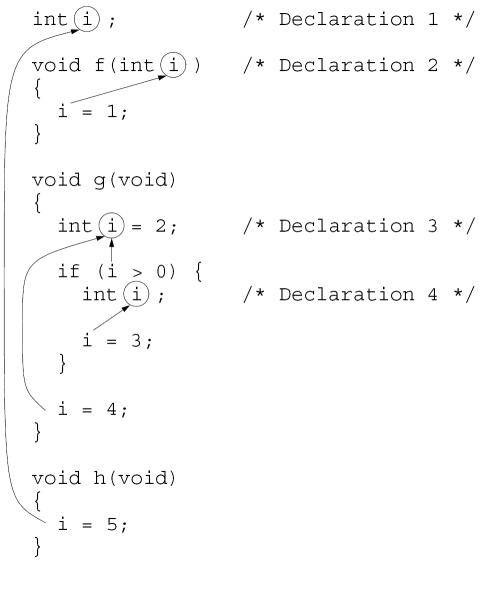

- In a C program, the same identifier may have several different meanings.
- C's scope rules enable the programmer (and the compiler) to determine which meaning is relevant at a given point in the program.
- The most important scope rule: When a declaration inside a block names an identifier that's already visible, the new declaration temporarily "hides" the old one, and the identifier takes on a new meaning.
- At the end of the block, the identifier regains its old meaning.

## Scope

- In the example on the next slide, the identifier i has four different meanings:
  - In Declaration 1, i is a variable with static storage duration and file scope.
  - In Declaration 2, *i* is a parameter with block scope.
  - In Declaration 3, i is an automatic variable with block scope.
  - In Declaration 4, i is also automatic and has block scope.
- C's scope rules allow us to determine the meaning of i each time it's used (indicated by arrows).

## Organizing a C Program

- Major elements of a C program:
  - Preprocessing directives such as #include and #define
  - Type definitions
  - Declarations of external variables
  - Function prototypes
  - Function definitions

### Organizing a C Program

- C imposes only a few rules on the order of these items:
  - A preprocessing directive doesn't take effect until the line on which it appears.
  - A type name can't be used until it's been defined.
  - A variable can't be used until it's declared.
- It's a good idea to define or declare every function prior to its first call.
  - C99 makes this a requirement.

### Organizing a C Program

- There are several ways to organize a program so that these rules are obeyed.
- One possible ordering:
  - #include directives
  - #define directives
  - Type definitions
  - Declarations of external variables
  - Prototypes for functions other than main
  - Definition of main
  - Definitions of other functions

### Organizing a C Program

- It's a good idea to have a boxed comment preceding each function definition.
- Information to include in the comment:
  - Name of the function
  - Purpose of the function
  - Meaning of each parameter
  - Description of return value (if any)
  - Description of side effects (such as modifying external variables)

- The poker.c program will classify a poker hand.
- Each card in the hand has a *suit* and a *rank*.
  - Suits: clubs, diamonds, hearts, spades
  - Ranks: two, three, four, five, six, seven, eight, nine, ten, jack, queen, king, ace
- Jokers are not allowed, and aces are high.
- After reading a hand of five cards, the program will classify the hand using the categories on the next slide.
- If a hand falls into two or more categories, the program will choose the best one.

- Categories (listed from best to worst):
  - straight flush (both a straight and a flush)
  - four-of-a-kind (four cards of the same rank)
  - full house (a three-of-a-kind and a pair)
  - flush (five cards of the same suit)
  - straight (five cards with consecutive ranks)
  - three-of-a-kind (three cards of the same rank)
  - two pairs
  - pair (two cards of the same rank)
  - high card (any other hand)

• For input purposes, ranks and suits will be single letters (upper- or lower-case):

Ranks: 2 3 4 5 6 7 8 9 t j q k a Suits: c d h s

- Actions to be taken if the user enters an illegal card or tries to enter the same card twice:
  - Ignore the card
  - Issue an error message
  - Request another card
- Entering the number 0 instead of a card will cause the program to terminate.

• A sample session with the program:

Enter a card: 2sEnter a card: 5sEnter a card: 4sEnter a card: 3sEnter a card: 6sStraight flush

Enter a card: <u>8c</u> Enter a card: <u>as</u> Enter a card: <u>8c</u> Duplicate card; ignored. Enter a card: <u>7c</u> Enter a card: <u>ad</u> Enter a card: <u>3h</u> Pair

Enter a card: <u>6s</u> Enter a card: <u>d2</u> Bad card; ignored. Enter a card: <u>2d</u> Enter a card: <u>9c</u> Enter a card: <u>4h</u> Enter a card: <u>ts</u> High card

Enter a card: <u>0</u>

- The program has three tasks:
  - Read a hand of five cards
  - Analyze the hand for pairs, straights, and so forth
  - Print the classification of the hand
- The functions read\_cards, analyze\_hand, and print\_result will perform these tasks.
- main does nothing but call these functions inside an endless loop.

- The functions will need to share a fairly large amount of information, so we'll have them communicate through external variables.
- read\_cards will store information about the hand into several external variables.
- analyze\_hand will then examine these variables, storing its findings into other external variables for the benefit of print result.

### Program: Classifying a Poker Hand

  A Modern Approach Second Edition
```

- How should we represent the hand of cards?
- analyze\_hand will need to know how many cards are in each rank and each suit.
- This suggests that we use two arrays, num\_in\_rank and num\_in\_suit.
  - num\_in\_rank[r] will be the number of cards with rank r.
  - num\_in\_suit[s] will be the number of cards with suit s.
- We'll encode ranks as numbers between 0 and 12.
- Suits will be numbers between 0 and 3.

- We'll also need a third array, card\_exists, so that read\_cards can detect duplicate cards.
- Each time read\_cards reads a card with rank r and suit s, it checks whether the value of card\_exists[r][s] is true.
  - If so, the card was previously entered.
  - If not, read\_cards assigns true to card\_exists
    [r][s].

- Both the read\_cards function and the analyze\_hand function will need access to the num\_in\_rank and num\_in\_suit arrays, so they will be external variables.
- The card\_exists array is used only by read\_cards, so it can be local to that function.
- As a rule, variables should be made external only if necessary.
